

This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1882 Excerpt: ...Thus it is obvious that the values of the coefficient of refraction resulting from the mutual observations between the stations in the plains could not be employed in the reduction of the vertical angles at those stations to the snowy peaks. Consequently the heights of all the peaks which were observed at the hill stations--in Sikkim, and afterwards at the western extremity of the principal series--were regarded as fixed by the observations at those stations, and were employed in calculating the probable values of refraction in the observations to the same peaks from the stations in the plains; and then these values were employed in obtaining coefficients of refraction to be used in reducing the observations to such of the peaks as were observed only at the stations in the plains. (2). Other Chains of Triangles.--Of these the most important was the triangulation to the subsidiary stations in Sikkim, at the eastern extremity of the Series, which was undertaken by the Surveyor General in person. It emanated from a base formed on the line cxviii to Cxxiii, and was executed with the largest theodolites which could be conveniently transported to the hill stations; thus Troughtons 36-inch theodolite was employed at Darjeeling, an 18-inch theodolite at Senchal and Birch hill, and a 12-inch at Tonglo, in measuring both the angles of the triangles and those to the snowy peaks. On the western extremity of the Series auxiliary stations were fixed on the well known mountains of Nagtibba, Kidarkanta, Sirkanda &c, from which observations were taken--some by Colonel Everest when Surveyor General--to Gangotri, Jannotri, and all the other prominent peaks of the Himalayas in this region. Observations were also taken at the hill stations of Jagesar and...
